

Workout App

The workout app produced seeks to serve as a simple to use tool for individuals looking to document their basic workouts and set goals for weekly exercises. It makes it simple for users to go back and look at how much weight they used on a certain exercise on a given date, allowing them to measure progress. The app supports three workout modes: timed, sets, and weighted sets. The main driver behind this design was to replace a spreadsheet based system I previously used to track workouts, and so I designed it by recreating all of the features I use in the spreadsheet.

Namely,

- Workout logging
- Keeping track of time spent
- Keeping track of weekly gym attendance
- Keeping track of how many weeks in a row I've been to the gym or exercised
- Keeping track of how much weight I can handle

The main screen of the application is the workout tab, which allows users to start a workout. This was chosen to be the main screen as it's the primary reason for opening the app. The other two tabs are the secondary use cases of opening the app, checking history, or checking goals.

On the workout tab, you're pushed through the interface at most one level deep, so you can always easily find your way around and it's not too much nesting to feel overwhelmed. I took inspiration from the Apple Fitness app on the watch, where everything is one to two taps away from the main screen. I rely on mobile native design such as swiping gestures for deletion patterns.

The primary color used throughout the application is green on a black background. As discussed in one of the first lectures, green represents energy and that energy is exactly the motivation needed to push yourself to workout. Rather than focus on many different colors, the app is monochromatic, using color sparingly but when it's used, it has meaning. Typically, something is a different color if its interactable or if it should draw additional attention such as a main title. The fonts used throughout the application are meant to make the interface easy to read and prevent any fatigue while using the app, as the energy should be spent on the workout, not the application.

It's intended that each user uploads their own exercises, as the equipment and exercises that someone will do vary widely based on what they're training for and the app does not seek to preload every exercise. However, as part of the requirements, I have added several preloaded exercises so you can understand how the application works.

Since the beta, there have been many bug fixes and features implemented. All of those are documented in the below changelog.

Changelog

- Implemented sets increment/decrement and saving of this information to exercise store
- Comments added throughout application
- Fixed issue where history can overlap tab bar
- Implemented pushing user to history view after workout is finished
- Implemented historical workout overview (can navigate back to previous workout overview screens from History tab)
- Fixed feedback on styling of history page, each history element takes less space and used more white instead of gray
- Fixed issue where chevron/arrow indicator from navigation links on history page was practically invisible (dark gray on black)
- Implemented deleting individual history items with swipe
- Implemented clear history, with alert confirmation, can now delete all history items at once
- If no exercises performed a text will be shown on overview instead of being blank
- Most recent workouts are now shown first on a given day's history
- Fixed issue where old workouts timers run indefinitely, so when you finish a new workout the time incremented on the historical workout
- Fixed issue where weight text was black in weighted sets
- Allow users to set goals by tapping on Current Goal
- Added Change Goal option at top right of Goals screen (as secondary method per Teams discussion feedback)
- Implemented app icon (per feedback), app icon uses COSC 6355 title
- Added splash screen
- Added information about weight, duration, and sets to historical workout overview screen
- Users can add new exercises
- Custom Images are saved to device sandbox, so users can have custom pics for their exercises
- Validated user input, show alerts on invalid input
- Reduced text in preloaded descriptions (per teams feedback)
